

ABSTRACT OF THE DISCLOSURE

Architecture that facilitates management of a build process according to a level of trust of a build entity. The build process processes one or more build entities, each of which is associated with a level of trust. These associations are stored in a policy file that is run against the one or more entities at the start of the build process. The build process runs at a permission level that is representative of the lowest level of trust of the build entities. The levels of trust include at least trusted, semi-trusted, and untrusted levels. If the lowest level is untrusted, the build process fails, and the user is notified.
